

The Uses and Abuses of Biology: Neuroscience, Parenting and Family Policy in Britain

A 'Key Findings' Report

**By Ellie Lee and Jan Macvarish, University of Kent,
Pam Lowe, Aston University**

Summary

The study summarised here took as its starting point the growing frequency with which claims about neuroscience, and what it is said to tell us about children, populate policy documents and statements by senior officials responsible for health and welfare services. The study was conducted by sociologists at the University of Kent and Aston University and funded through the Faraday Institute's 'Uses and Abuses of Biology' programme.

The key conclusions of the study are:

- Brain claims enter a policy context which is already convinced that something must be done about parents.
- Brain claims, challenged elsewhere as lacking scientific foundation, are imported and repeated in the British context.
- Brain claims serve a rhetorical and metaphorical function, opening up the parent child relationship to earlier and more intimate interventions.
- Brain claims intensify the demands on parents by threatening lifelong consequences and reinterpret the ordinary practices of loving families as meaningful only for brain development.
- Brain claims emphasise emotions, not IQ, as fundamentally determinate of future health, wealth and happiness, thereby placing the emotions of new mothers under considerable pressure and scrutiny.

Further information about the project and its findings can be found at:

Background to the study

Neuroscience can now explain why early conditions are so crucial: effectively, our brains are largely formed by what we experience in early life....scientific discoveries suggest it is nurture rather than nature that plays the lead role in creating the human personality....It has been said that 'the greatest gift for a baby is maternal responsiveness'. The more positive stimuli a baby is given, the more brain cells and synapses it will be able to develop.

(Graham Allen MP and Iain Duncan Smith MP, 'Early Intervention: Good Parents, Great Kids, Better Citizens', published by The Centre for Social Justice and The Smith Institute, 2008, p57)

The early years of life are a crucial period of change; alongside adolescence this is a key moment for brain development. As our understanding of the science of development improves, it becomes clearer and clearer how the events that happen to children and babies lead to structural changes that have life-long ramifications. Science is helping us to understand how love and nurture by caring adults is hard wired into the brains of children. We know too that not intervening now will affect not just this generation of children and young people but also the next. Those who suffer multiple adverse childhood events achieve less educationally, earn less, and are less healthy, making it more likely that the cycle of harm is perpetuated, in the following generation.

(Sally Davies, Chief Medical Officer, foreword to 'The 1001 Critical Days: The Importance of the Conception to Age Two Period', a cross-party manifesto by Andrea Leadsom MP, Frank Field MP, Paul Burstow MP, Caroline Lucas MP, published by the 1,001 Critical Days Campaign, 2013, p2)

The first extract above is taken from a document by the Centre for Social Justice and The Adam Smith Institute, published six years ago. (One of its authors is, of course, now a senior member of the Government, the other the author of Government-commissioned documents advocating 'early intervention' and Chair of the Early Intervention Foundation [1]). The second is from a more recent document, authored by a group of MPs and endorsed by twelve further members of the House of Commons and the House of Lords and by 36 third sector organisations advocating early intervention.

Both contain a set of very similar claims, expressed using particular language, as follows:

- 'Early conditions' or the 'early years of life' are described as 'crucial';
- It is said that early experience 'largely forms' our brains and does this biologically, and so it is said this experience leads to 'structural changes' in the brain;
- The claim is repeated that 'neuroscience' or 'the science of development' has told us these things about the brain and so they are known or understood;
- It is stated that the brain is directly affected in this way by what the parents of children do; 'positive stimuli' leads to 'brain cells and synapses' and 'love and nurture' is claimed to be 'hardwired' into the brain;
- 'Intervening early' is described, on the basis of these contentions about the brain and what parents do, to be a necessity to arrest a 'cycle of harm' that otherwise carries through 'generations'.

Biologised claims of this kind centring on statements about early brain development have thus emerged as a dominant theme for English policy making, leading to an argument about the need to reorient policy goals to intervene in parental 'nurture'. Given the apparent rapid emergence and spread of this biologisation of policy, this study sought to explore both the content and context of this ostensible new departure for policy making. The aims of the study were:

- To review the existing literature about the 'scientisation' of parent-child relationships historically and identify the central themes that emerge;

- To trace the adoption of ‘brain-based’ claims articulating the need to change parenting practices by English education and public health policy from 1997 onwards, identifying a time-line for their appearance and expansion in these policy fields;
- To detail the reference points and purported evidence-base for ‘brain-based’ claims, identifying similarities and differences between policy documents, and between policy fields;
- To identify the discursive role of ‘brain-based’ claims in framing new policy agendas, specifically by detailing the conceptualisation of ‘poverty’, ‘inequality’, and ‘social mobility’ associated with these claims;
- To detail the challenge made by current policy discourses to the normative assumption that parenting style is a ‘private matter’.

We highlight four main themes that emerge from the study:

- Early intervention as a cause in search of an argument
- The questionable claims of infant neuroscientism
- The dramatization of ‘nurture’
- Continuity and change in official concerns

Methods

The study comprised three areas of analysis:

1. Policy documents

A sample of policy documents (n=41), representative of the formation of parenting policy across a number of domains (social exclusion, health, maternity services, early years, crime and justice) was gathered from the period 1997 to 2013 and subjected to qualitative content analysis using NVIVO software. Most documents were published or commissioned by government departments but in addition, a small number emanating from early intervention advocacy groups were included. The analysis focused on the way the relationship between parenting and

social problems was discussed and when, where and how claims about the infant brain interacted with these concerns. [A full list of documents can be found in the Appendix].

2. Literature review: the ‘first three years movement’ and ‘neuroscientism’

Literature was reviewed that considers the academic discussion of brain-based claims-making and policy intervention in early childhood. Literature was found by searching Google Scholar using variations of the keywords ‘brain’, ‘neuroscience’, ‘child’, ‘0 to 3’ and ‘early intervention’. Results were evaluated and selected for their relevance to the topic of brain-based early intervention. Bibliographic references of relevant items were then followed up to further expand the sample. The search was restricted to work produced in the English language, finding work by scholars from the USA, Canada, the UK and New Zealand, and from a diverse range of academic areas, including sociology, history, psychology and social psychology, media/cultural studies, philosophy and neuroscience. [The literature reviewed is detailed in the Bibliography at the end of this document].

Two conceptual categories emerged from the literature and proved useful in further analysing the sample. These were a) the specific critique of the ‘first three years movement’ and its claims about parenting and b) the wider critique of ‘neuroscientism’ with specific reference to claims about infant brain development. (See footnote [2] for an explanation of these categories). The analysis then focused on identifying the grounds on which neuroscientific evidence claims have been challenged and the ways in which the policy orientation towards the early years has been problematised.

3. Historical literature: the ‘child saving movement’

The intention of this part of the study was not to produce an exhaustive review of the historical literature on childhood but rather to gain an overview of previous ideological constructions of the parent-child relationship as a problem requiring political attention. The period from the mid-eighteenth century to the present day was focussed on to identify particular historical moments when the early years and the quality of parental nurture became the object of political concern. The search took as its starting point eight texts on the history of modern

childhood. From these, four themes were identified as resonating with the contemporary argument for brain-based early intervention: 'child saving'; the 'scientisation' of motherhood; the intergenerational transmission of 'cycles of harm'; and 'parental determinism'. These themes were then explored further through more specific literature. [The literature reviewed is detailed in the Bibliography at the end of this document].

Findings

1. Early intervention and neuroscience: A cause in search of an argument

As indicated above, claims about the developing brain have become widespread in policy documents. However, the analysis showed that concern with parental behaviour - with 'nurture' - was well-established *before* the emergence of brain claims in the British context. The first direct reference to the brain found in the sample of policy documents reviewed was in the 2003 'Birth to Three Matters' literature review, published by the Department for Education and Skills. In contrast, the term 'parenting' was found frequently across the whole sample. 'Parenting' occurred as a term used a total of 1566 times in the documents analysed ('brain' occurred 396 times). A closer examination of the way it was used, paying attention to the use of 'parenting' as a prefix to other terms, revealed the following:

- **'Parenting' is discussed directly as a problem.** In this usage of the term, 'Parenting' was constructed as a problem in need of solutions. For example, the terms used in conjunction with 'parenting' were: *Parenting support; Parenting order; Parenting intervention; Parenting issues; Parenting programmes; Parenting intervention.*
- **'Parenting' as a skill.** 'Parenting' used in this way denoted a particular activity or set of practices which can be evaluated and improved. The terms used in this way were: *Parenting style; Parenting skills; Parenting competencies; Parenting strategy; Parenting capacity; Parenting objectives.*

- **‘Parenting’ in partnership with experts.** ‘Parenting’ was discussed as an activity subject to expert knowledge. For example: *Parenting education; Parenting facilitators; Parenting classes; Parenting Institute; The Science of Parenting; Parenting guides.*

The depiction of British parenting as deficient or problematic in this way was thus found to be a consistent feature of the documents reviewed. While differing degrees of negativity about the state of contemporary family life were evident in the documents, as they were produced by parties and think-tanks across the political spectrum, it was very apparent that a consensus had clearly formed from 1997 onwards around the idea of a ‘parenting deficit’. The strongly held view was that raising children is both very difficult and of paramount importance to not just individual families, but to society in general. It was evident that ‘parenting’ had been politicised.

This finding accords with arguments made in the academic social policy literature which identifies a broad shift from an ‘implicit’ to an ‘explicit’ family policy. Emphasis has been placed on the importance of the disappearance of a traditional British ‘reluctance’ in regards to policy making about the family, and its replacement with more overt agendas seeking to address perceived problems of family life. The period of new Labour Government (1997-2010) has been identified elsewhere as constituting a watershed in changing the nature of policy in this respect [3]. Our analysis suggests similarly that the problematisation of parenting and the demand that policy attention be turned towards the inner workings of the family were established in Britain well *before* claims that ‘new evidence from neuroscience’ proves the primacy of parental influence on the infant brain, were deployed.

In this respect, the ‘cause’ – intervening in the early years to influence ‘parenting’– can be said to have manifestly established itself in policy thinking before the ‘argument’ – neuroscientific evidence that the early years are ‘critical’ – was made by policy-makers. The first three years movement can be said to represent the concentration of the prior anxiety about the quality of intimate, intergenerational relationships between parents and children, into the visible, biological form of the brain.

2. Infant neuroscientism: The repetition of questionable claims

What emerged from our analysis of the 24 policy documents which contain references to the brain, and from the review of literature produced in response to ‘the first three years movement’, was a significant disjuncture between the strength of the claims made in policy circles, and the already existing and developed critical analysis of these claims. Only in the first document to contain brain claims, the 2003 ‘Birth to Three Matters’ literature review mentioned earlier, was there any reference to sceptical or critical views. This report accurately reports Professor John Bruer’s challenges to the claims that brain research has produced ‘new evidence’ about the significance of the early years (p116) and that the first three years of life are critical to brain development (p119). The subsequent 23 documents, while repeating many claims from the earlier US ‘first three years’ campaigning, failed to acknowledge that there was a well-publicised contestation over such brain claims in the US [4]. Instead, brain claims tended to be made in increasingly simplified terms, often with no citations of the scientific literature from which they draw authority, leading us to identify this as ‘neuroscientism’, not ‘neuroscience’ [5].

According to John Bruer’s book *The Myth of the First Three Years* (1999), which traced the emergence and development of the ‘first three years movement’ in the US, and contrasted its claims with a review of the scientific literature on brain development, the most-repeated claims about the early years describe the brain as undergoing a ‘synaptical explosion’, during a ‘critical period’ of growth which requires stimulation from ‘enriched environments’. Despite critique from Bruer and others, these claims were evident in English documents from 2003 onwards, as can be seen in the quotations below, taken from the policy documents in the sample.

- **Early brain development is characterised by an explosion of synaptical growth.**

By the age of 3, the young child has around twice the number of neurons of an adult – making the early years critical for the development of the brain, language, social, emotional and motor skills.

(2010 ‘Healthy Lives, Healthy People’, p18. No source cited for the claim)

Children’s brains develop faster in the first two years than at any other stage and they learn more quickly.

(2007 ‘Children’s Plan 0-7 Expert Group Report’, p10. No source cited for claim)

'Synaptic growth' is interpreted by the 'first three years movement' to mean that the early years represent a 'use it or lose it' opportunity to shape infant brains. Many scientists have disputed these claims to truth, however, arguing that more synapses do not mean more brain power; increased dendritic density occurs at any age; and that only certain areas of the brain show increased synaptic density during the early years.

- **Early brain development is characterised by 'critical periods'.**

Recent research in neuroscience also shows that the first three years of a child's life are critical in terms of the development of the brain's capacity to learn both cognitive and social and emotional skills...

(2007 'Policy Review of Children and Young People', p14. Source cited for claim: 'The importance of caregiver-child interactions for the survival and healthy development of young children – A review', World Health Organization, 2004)

Critics of the 'first three years movement' contend that while aspects of language acquisition and visual development are particularly rooted in the early years, neuroscientists agree that critical periods are the exception, not the norm in the development of other human faculties.

- **Babies' brains require particular attention to providing stimulating environments for normal development to occur.**

Many parents are doing a brilliant job, but in some homes the child is strapped in a pushchair and pointed at a blank wall during those precious, irreplaceable first two or three years. It is a wasted opportunity, for which they and we pay the price over successive years.

(2008 'Early Intervention', First Edition, p111. No source cited for the claim)

Evidence on neurological development shows how babies build connections in their brain which enable the development of speech and language, self-confidence and good relationships with other children and adults...It is imperative that children's healthy development in their first years of life is supported...Parents are informed about the importance of talking to their child and following the child's lead in their physical play whilst developing the parents' understanding of brain development.

(2011 'The Early Years: Foundations for life, health and learning', p21. No source cited for claim)

While there is evidence that extremely deprived environments (such as those, notoriously, revealed in Romanian orphanages) experienced in infancy can permanently impair brain development, studies show that even children raised in these conditions could improve when removed from them and cared for in more normal conditions of family life. The massive historical and global variation in child rearing practices indicates that normal human brains develop in essentially ‘ordinary’ environments, which are sufficient to stimulate brain development. There is no evidence to suggest that increased stimulation increases brain capacity.

By comparing the claims made in English policy documents with those made by the earlier US ‘first three years movement’, and by holding them up against the already existing scientific critique of such claims, we can conclude that there is little ‘new’ about the brain claims currently in circulation in England. It is also evident that their attachment to scientific method and evidence is largely rhetorical, with the vulnerable infant brain serving primarily as a metaphor for a prior anxiety about the potentially harmful influence of parents. This metaphorical deployment of claims about brain development is explicitly evident here:

Pregnancy, birth and the first 24 months can be tough for every mother and father, and some parents may find it hard to provide the care and attention their baby needs. But it can also be a chance to affect great change, as pregnancy and the birth of a baby is a critical ‘window of opportunity’ when parents are especially receptive to offers of advice and support.

(2013 ‘The 1001 Critical Days’ p5.)

While the idea of the early years as a ‘critical window’ usually connotes a claimed (but as we see above, disputed) biological fact of brain development, here it is *the parents* who must be opened up to external influence during the ‘critical period’ of the early years of their baby’s life.

3. The dramatization of ‘nurture’

In addition to the repetition of old claims, the study identified some new features in English brain claims-making. Whereas many people are familiar with the commercial exploitation of

brain claims to market baby toys promising the creation of ‘Baby Einsteins’ or ‘Baby Mozarts’, in the English policy context, there has been little emphasis on raising smarter babies. It is a curious feature of this neuroscientific claims-making that it tends not to recommend high-tech or medical interventions. Instead, the singular focus is on programmes of parental education and support which reinterpret very ordinary activities such as talking, singing, cuddling and reading as neurologically critical; in this way ‘nurture’ (and the alleged lack of it) becomes dramatized as having profound consequences for the individual and for society.

Hence, the argument is made that emotional development, shaped by parental nurturing practices and rooted in the structure of the brain, underpins cognitive development. This is achieved through the promotion of a biologized and gender-neutral version of parent-child attachment as the mechanism through which nature (the brain) is nurtured (by parental love). Invocations of attachment theory and the role of cortisol, (the ‘stress hormone’), are here deployed to advocate attentive parenting by both mothers and fathers. This approach implicitly de-normalises the kinds of things which parents already do because they are fun or rewarding expressions of love, by suggesting that a) they do not happen often enough and b) they require the intervention of trained professional to teach parents of their importance. It also constructs ordinarily testing experiences and the ‘emotional ups and downs’ of pregnancy and parenthood as potentially catastrophic. The extracts below illustrate this process of dramatization.

Crying babies

The development of a baby’s brain is affected by the attachment to their parents and analysis of neglected children’s brains has shown that their brain growth is significantly reduced. Where babies are often left to cry, their cortisol levels are increased and this can lead to a permanent increase in stress hormones later in life, which can impact on mental health. Supporting parents during this difficult transition period is crucial to improving outcomes for young children.

(2010 ‘The Foundation Years’, p41. Source cited for claims, Perry, B. (2002)

Childhood experience and the expression of genetic potential: what childhood neglect tells us about nature and nurture. *Brain and Mind* 3: 79–100)

Here we see how an ordinary, expected occurrence – a baby crying – is associated with extremely neglectful care (reminiscent of Romanian orphanages, which are cited frequently in

the sample of documents we analysed). Its consequences are thus constructed as dramatic, permanent, biological and potentially catastrophic. By intensifying the significance of how new parents care for their babies, for the individual child and, it is implied, for society, the case is made for professional intervention in the normal experience of parents learning how to respond to their baby's needs.

Pregnancy and maternal mood

In the following quotation, we can see another significant development in brain-claiming – the claim that the mother's emotional state *during pregnancy* is potentially harmful to the brain of the developing fetus:

The CHPP [Child Health Promotion Programme] needs to reflect new evidence that has emerged about neurological development and the importance of forming a strong child– parent attachment in the first years of life. It should also incorporate the information that we have about the adverse effect that maternal anxiety and depression in pregnancy can have on child development. A child's brain develops rapidly in the first two years of life, and is influenced by the emotional and physical environment as well as by genetic factors. Early interactions directly affect the way the brain is wired, and early relationships set the 'thermostat' for later control of the stress response. This all underlines the significance of pregnancy and the first years of life, and the need for mothers and fathers to be supported during this time.

(2008 'Child Health Promotion Programme: Pregnancy and the First Five Years of Life', p9. No source cited for claim)

It may not seem obvious that the emotions of pregnant women could impact on the infant brain, but evidence-claims are increasingly made that maternal stress and depression produce chemicals which inhibit healthy fetal brain development. Health professionals are therefore now trained in the significance of parental behaviour for healthy infant brains from conception onwards:

A child's experience and environment – both in the womb and in early life – lay the foundation for life. Mothers and fathers are the most important influences on a child's well-being and development. Loving, caring and secure parenting, as well as good nutrition and protection from toxic substances such as tobacco, are essential for a child's growth, well-being and development. These factors have a direct and lasting impact on a child's physical development (particularly neurological development) and on his or her

future health, learning and behaviour (see Part 2). In recent years, advances in neuroscience have increased our understanding of the links between early brain development and later life outcomes, and have shown the importance of providing very young children with consistent, positive and loving care.

(2011 'Preparation for birth and beyond: A resource pack'. Section 2/4/29. No source cited for claim)

Overall, our study indicates that claims of this kind reinforce pre-existing ideas of early infancy being determinate of future life chances but also confirm the construction of the parent as the key mechanism through which this determinism is leveraged on the individual child, for good and for bad. This instrumental, biologised way of thinking about family life also expands and intensifies the obligations of parents to new levels. If parents are, as it is sometimes claimed, 'the architects' of their children's brains, and children's brains form the future of society, then there can be no defence against efforts by government to protect those brains from harm. Why, after all, would a conscientious, loving parent refuse 'support' and risk harming their child's brain?

4. Continuity and change in official concerns: Old wine in new bottles?

Our review of historical literature about the late 19th and early 20th centuries drew out clear resonances between contemporary demands for early intervention and those of earlier incarnations of the child-saving/parenting improving imperative. Previous periods of intense political concern with the quality of parenting (such as the anxiety about motherly instincts in the late 19th century) were also periods of anxiety about rapid social change, concern for the proliferation of the 'wrong sort of people' and a view of the child as the key to future progress or degeneration.

Inevitably, the social project to rescue the child from inadequate parenting produces contestations over the legitimate authority of parents relative to the state. Earlier incarnations of scientific expertise, in the form of medicine, hygiene and psychology, were deployed to defuse this conflict in much the same way that the novelty of neuroscience today is exploited to

make the case for early intervention and parent training. In this regard, research confirmed our suspicion that current brain claims could be considered to be 'old wine in new bottles'.

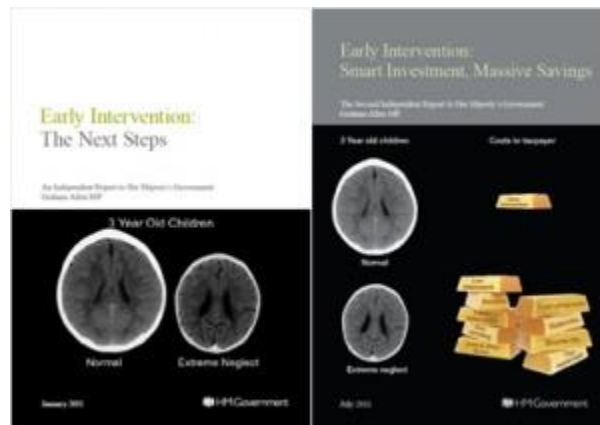

However, what can be said to be new in the recent period is an intensified focus on intimate interactions between the parent and child (such as feeding, touch, speaking), together with a dramatized focus on maternal mood and emotion, bringing with it an expanded concern with the practices of a larger proportion of the parenting population. This has occurred to the extent that the universal provision of advice and support is argued for, and demands are even made for all children to be taught 'brain-based parenting' as part of the school curriculum.

Social movements which biologised notions of social progress in previous historical periods argued unapologetically for intervening in childhood to strengthen the national 'race'. What is new today in the invocation of biology is that the concern appears to be more with the capacity of those who 'nurture' to ensure the proper development of 'nature'. In contemporary brain claiming, the overriding importance of the infant brain rests in the belief that it is biologically determinate of the future adult. But while it is argued that the brain is essentially 'fixed' in early childhood, the window of 'plasticity' present in the early years is conceptually even more important, as it is this which is mobilized to make the case for early intervention and parent training.

In the present period, we can see that the apparent biologization of the child's needs is not paralleled in a naturalization of a parent's ability to meet them. Whereas in the 1950s and 1960s, figures such as John Bowlby posited that attachment was a natural instinct in all babies and most mothers, given the right conditions, and later, 1970s biologised theories of attachment claimed that bonding was driven by hormones, today's neuroscientific-based theories see attachment as a much less natural or reliable occurrence. Whereas Bowlby predicted attachment problems in some mothers, early intervention policy is driven by the imperative to monitor all mothers. Nature is therefore not inherently functional, but must be nurtured through the encouragement of particular practices and the guidance of 'neuroscientifically-informed' experts.

Footnotes

[1] Front covers of documents commissioned by HM Government, authored by Graham Allen MP (published 2011).

Details of the work of the Early Intervention Foundation can be found at: <http://www.earlyinterventionfoundation.org.uk/>

[2] Thornton (2011) uses the term the ‘first three years movement’ to capture the alliance of child welfare advocates and politicians which draws authority from the wider excitement about neuroscience to argue that social problems are best addressed through ‘early intervention’ programmes to protect or enhance emotional and cognitive aspects of children’s brain development. Tallis (2011) makes a helpful distinction between *neuroscience*, which has brought real insights to our understanding of brain function and dysfunction, and *neuroscientism*, which is an ideological attempt to discover the essence of humanity in the brain.
